Research Objective

This study aims to explore the user experience of an AI fashion recommendation agent that distinguishes users' everyday style preferences from their current situational needs and selectively gathers additional information through either conversational or image-based questions.

The research objectives of this survey are as follows. First, we examine how separately managing users' gradually refined baseline preferences and temporary preferences shaped by the current situation—and allowing users to review and revise them affects users' sense of control over the recommendation process.

Second, when additional information is needed to understand users' preference criteria, we investigate whether selectively providing text-based questions or image-based choices can reduce the burden of expressing intent and increase users' perception that the system understands their intentions.

In addition, the pre-survey is designed to assess participants' general interest and knowledge in fashion to articulate their preferences, context-dependent style selection characteristics, and potential situations in which they might use an AI fashion recommendation agent. The post-survey evaluates the usability, cognitive workload, and overall user experience of the proposed system.

Survey Structure

1. Pre-survey

- Demographics & prior experience
- Fashion knowledge and familiarity
- Preference awareness and articulation ability
- Context-dependent fashion decision behavior
- Situations in which users would use an AI fashion recommendation agent

2. Post-survey

- Comparison of baseline and proposed system
- Self-congruence & context appropriateness
- Perceived control
- Preference expression & perceived AI understanding
- Adaptive text–image interaction
- System usability (SUS)
- Open-ended feedback
- Workload (NASA-TLX)
